3Ocean University of China, Qingdao, 266101, PR China

A strictly anaerobic, mesophilic, carbohydrate-fermenting, hydrogen-producing bacterium, designated strain RL-CT, was isolated from a reed swamp in China. Cells were Gram-stain-negative, catalase-negative, non-spore-forming, non-motile rods measuring 0.7–1.0 μm in width and 3.0–8.0 μm in length. The optimum temperature for growth of strain RL-CT was 37 °C (range 25–40 °C) and pH 7.0–7.5 (range pH 5.7–8.0). The strain could grow fermentatively on yeast extract, tryptone, arabinose, glucose, galactose, mannose, maltose, lactose, glycogen, pectin and starch. The main end products of glucose fermentation were acetate, H2 and CO2. Organic acids, alcohols and amino acids were not utilized for growth. Yeast extract was not required for growth; however, it stimulated growth slightly. Nitrate, sulfate, sulfite, thiosulfate, elemental sulfur and Fe(III) nitrotriacetate were not reduced as terminal electron acceptors. Aesculin and gelatin were not hydrolysed. Indole and H2S were produced from yeast extract. The G+C content of the genomic DNA was 51.2 mol%. The major cellular fatty acids were iso-C15:0, anteiso-C15:0 and C16:0. The most abundant polar lipid of strain RL-CT was phosphatidylethanolamine. 16S rRNA gene sequence analysis revealed that the isolate belongs to the uncultured Blvii28 wastewater-sludge group (http://www.arb-silva.de/) in the family Rikenellaceae of the phylum Bacteroidetes, and shared low sequence similarities with the related species Alistipes shahii (81.8%), Rikenella microfusus (81.7%) and Anaerocella delicata (80.9%). On the basis of these data, a novel species in a new genus of the family Rikenellaceae is proposed, Acetobacteroides hydrogenigenes gen. nov., sp. nov. The type strain of the type species is RL-CT (=JCM 17603T=DSM 24657T=CGMCC 1.5173T).

The phylum Bacteroidetes consists of four recognized classes Bacteroidia, Flavobacteria, Sphingobacteria and Cytophagia (Krieg et al., 2010). The majority of strictly anaerobic species are in the order Bacteroidales of the class Bacteroidia. The family Rikenellaceae of the order Bacteroidales is a phylogenetical and phenotypical group, which contains three genera Rikenella (type genus), Alistipes and Anaerocella. At the time of writing, the genus Alistipes, comprises five species: Alistipes putredinis, Alistipes finegoldii, Alistipes oderondkii, Alistipes shahii and Alistipes indistinctus (Holdeman et al., 1984; Nagai et al., 2010; Rautio et al., 2003; Song et al., 2006; Krieg et al., 2010), which have been isolated mainly from various human clinical specimens. At the time of writing, both the genera Rikenella and Anaerocella contain only one species: strains of Rikenella microfusus have been isolated from faecal or caecal specimens (Kaneuchi & Mitsuoka, 1978), and Anaerocella delicata has been isolated from a methanogenic reactor of cattle farms (Abe et al., 2012). To date, all cultured members of the family Rikenellaceae are described as anaerobic, mesophilic, rod-shaped bacteria that usually ferment carbohydrates or proteins. Many uncultured taxonomic groups also exist in the family Rikenellaceae, including Blvii28, a wastewater-sludge group commonly found in anaerobic wastewater or waste treatment systems (Kaksonen et al., 2004; Narihiro et al., 2009; Shen et al., 2013), and freshwater environments.
(Hedlund et al., 2013). Based on taxonomy (using ARB and SILVA software), the Blvii28 group contains 7952 sequences; this represents the largest 16S rRNA gene sequence number among the family Rikenellaceae (http://arb-silva.de). However, no cultivated representatives from this group have been reported so far.

In marine and freshwater environments, a high abundance of Bacteroidetes organisms are detected; these are considered to be of high importance for the degradation of organic matter, such as complex polysaccharides (Cottrell & Kirchman, 2000; Kirchman, 2002). In this study, the isolation of a freshwater bacterium (strain RL-C<sup>T</sup>) belonging to the uncultured Blvii28 wastewater-sludge group in the family Rikenellaceae is described.

Strain RL-C<sup>T</sup> was originally obtained from a reed swamp in Qingdao, Shandong Province, China (36°00′00″N 120°00′00″E). The medium used for isolation and cultivation of strain RL-C<sup>T</sup> was prepared as described previously (Sekiguchi et al., 2000). Decomposed reed (~1 g) from swamp was transferred into 5 ml anoxic sterile medium and vortexed. The suspension solution of rotted reed was serially diluted 5-fold in noble agar (2 %, w/v; Difco) solid roll-tubes. In reed swamp environments, microbes are considered to be responsible for the degradation of plant polysaccharides, such as cellulose, pectin and starch. A solid medium supplemented with a mixture of xylan, pectin and yeast extract in low concentrations (0.005–0.01 %, w/v) was used to imitate the natural reed swamp and thus isolate the micro-organism. The cultures were incubated at 37 °C under anaerobic condition (N<sub>2</sub>/CO<sub>2</sub>; 80 : 20, v/v). Small, light-brown and lens-shaped colonies formed after one week of incubation. The colonies were picked and transferred to a liquid medium supplemented with the mixture of xylan, pectin and yeast extract described above; growth of cells in the liquid medium was observed after 4–7 days of anaerobic incubation at 37 °C. This roll-tube isolation step (transferring single colonies from solid to liquid medium) was repeated several times until the purified strain (RL-C<sup>T</sup>) was obtained. Strain RL-C<sup>T</sup> was maintained on the glucose (2 mM) and yeast extract (0.01 %, w/v) medium, and growth was observed in 4–7 days of incubation at 37 °C.

Cell morphology was examined under a fluorescent microscope (BX50F; Olympus). Transmission electron microscopy (TEM) was performed with a Hitachi H-7000 transmission electron microscope as described previously (Sekiguchi et al., 2003). The Gram staining reaction was performed by the method of Hucker (Doetsch, 1981). Cells of strain RL-C<sup>T</sup> were Gram-stain-negative, non-motile rods that did not form spores (0.7–1.0 × 3.0–8.0 μm) (Fig. 1a). TEM confirmed strain RL-C<sup>T</sup> possessed a Gram-negative type cell wall (Fig. 1b).

The physiological characteristics of strain RL-C<sup>T</sup> were examined as described previously (Sekiguchi et al., 2000). The temperature range for growth was determined between 20 to 55 °C (at 5 °C intervals, with an exception at 37 °C).

The pH range for growth was determined at 37 °C over the range pH 5.0—8.5 (in 0.5 pH unit intervals), and NaCl tolerance was tested in the presence of 0–3.0 % (w/v) NaCl (in 0.5 % intervals). The pH was adjusted at room temperature by adding HCl or NaOH to the autoclaved medium. The pH was measured at the beginning and end of the experiments. The growth of cells was evaluated based on the increase in optical density at 400 nm and the production of H<sub>2</sub>. Short-chain fatty acids, H<sub>2</sub> and CH<sub>4</sub> were measured as described previously (Qiu et al., 2014). Unless otherwise indicated, the organism was cultured anaerobically (N<sub>2</sub>/CO<sub>2</sub>; 80 : 20, v/v) at 37 °C without shaking. Aerobic growth was tested in a medium containing glucose (2 mM) and yeast extract (0.01 %, w/v) under aerobic conditions without adding reducing agents. For catalase detection test, 1 drop of 15 % (v/v) hydrogen peroxide solution was added to viable cells on a microscope slide; bubble formation indicates a catalase-positive reaction. Methanosarcina barkeri DSM 804 and Sporotomaculum syntrophicum DSM 14795<sup>T</sup> were used as catalase-positive and -negative controls, respectively. Production of indole and H<sub>2</sub>S, as well as hydrolysis of aesculin and gelatin, was determined according to the conventional methods described by Holdeman et al. (1977). Strain RL-C<sup>T</sup> grew anaerobically on glucose/yeast extract medium at 25–40 °C (optimum, 37 °C), at pH 5.7–8.0 (optimum, approximately
pH 7.0–7.5) and with 0–1.5 % (w/v) NaCl; no growth was observed below 25 °C or above 40 °C after 8 weeks of incubation. The isolate was a strict anaerobe; it could not grow in the presence of oxygen (20 %, v/v, in the gas phase) nor after N₂/CO₂ purging (without addition of reducing agents). Growth and H₂ production were observed with the following substrates (5 mM each unless specified otherwise): arabinose, glucose, galactose, mannose, maltose, lactose, glycogen (0.1 %, w/v), pectin (0.1 %, w/v), starch (0.1 %, w/v), yeast extract (0.1 %, w/v) and tryptone (0.1 %, w/v). Xylan was weakly fermented. In the medium supplemented with glucose, the major end products were acetate, H₂ and CO₂ (1 mol of glucose was converted to approximately 1.9 mol of acetate and 5.3 mol of H₂, electron recovery: 106 %). Yeast extract was not required, however it stimulated growth slightly. Strain RL-C<sup>T</sup> exhibited a fast growth rate; the specific growth rate (μ<sub>max</sub>) calculated was based on hydrogen production in a glucose (5 mM)/yeast (0.01 %) medium, this was estimated to be 1.8 day<sup>−1</sup>. None of the following substrates tested supported the growth of strain RL-C<sup>T</sup> in pure culture or co-culture with Methanospirillum hungatei DSM 864<sup>T</sup> (5 mM unless specified): xylose, ribose, fructose, sucrose, cellobiose, melezitose, melibiose, raffinose, salicin, amygdalin, inulin (0.1 %, w/v), cellulose (0.1 %, w/v), inositol, mannitol, sodium CM-cellulose (0.5 %, w/v), Casamino acids (0.1 %, w/v), glutamate, serine, alanine, H₂/CO₂ (1 atm, 80/20, v/v) plus acetate, formate, propionate, butyrate, iso-butyrate, lactate, pyruvate, crotonate, succinate, malate, fumarate, glycerol, ethylene glycol, methanol, ethanol, 1-propanol, 1-butanol, benzoate, hydroquinone (1 mM) and phenol (1 mM). Strain RL-C<sup>T</sup> did not use any of the following electron acceptors within 6 weeks of incubation on glucose/yeast extract medium (mM): nitrate (5), sulfate (5), sulfite (1), thiosulfate (2), elemental sulfur (5) and Fe(III) nitritotriacetate (2). Cells were catalase-negative, indole and gelatin were not hydrolysed. Indole and H₂S were produced from yeast extract.

For genomic DNA G + C content determination, DNA was extracted and purified according to Kamagata & Mikami (1991). The G + C content was determined by HPLC (LC-6A; Shimadzu) with a UV detector (Shintani et al., 2000). The genomic DNA G + C content of strain RL-C<sup>T</sup> was 51.2 mol% (SD ± 0.06 mol%). Fatty acids of cells were converted to methyl esters using HCl/methanol and identified by GC-MS (Hitachi M7200AFD/3DQMS system) (Hanada et al., 2002). For fatty acid methyl ester and polar lipid analyses, cells were harvested during the exponential phase of growth from cultures anaerobically grown on 5 mM glucose and 0.02 % (w/v) yeast extract at 37 °C. The major cellular fatty acids of strain RL-C<sup>T</sup> were iso-C<sub>15:0</sub> (50.6 %), anteiso-C<sub>15:0</sub> (13.2 %), C<sub>16:0</sub> (11.7 %), C<sub>15:0</sub> (4.8 %), iso-C<sub>16:0</sub> (4.8 %), iso-C<sub>17:0</sub> (4.6 %), C<sub>18:0</sub> (3.7 %), anteiso-C<sub>17:0</sub> (3.2 %). Polar lipids were extracted and analysed by the methods of Tindall (1990), using two-dimensional TLC (silica gel 60 F<sub>254</sub> plates, 0.2 mm, no. 5554; Merck). The most abundant polar lipid of strain RL-C<sup>T</sup> was phosphatidylethanolamine. Several unknown phospholipids, aminophospholipid and polar lipids were also detected (Fig. S1, available in the online Supplementary Material).

For 16S rRNA gene sequencing, the genomic DNA of strain RL-C<sup>T</sup> was extracted according to the method of Hiraishi (1992). 16S rRNA genes were amplified by PCR with Taq polymerase (Promega). The primers used in the PCR were the bacterial domain universal primer 8F and the prokaryote universal primer 1490R (Weisburg et al., 1991). The PCR product was sequenced directly on a Beckman CEQ-8000 DNA sequencer using a CEQ DTC quick-start kit (Beckman Coulter). The phylogenetic tree, based on 16S rRNA gene sequences, was reconstructed using the neighbour-joining method (Saitou & Nei, 1987) in the MEGA5 software package (Tamura et al., 2007). The confidence values of branches in the phylogenetic tree were determined using bootstrap analysis based on 1000 resamplings (Felsenstein, 1985). A total of 1440 base pairs of the 16S rRNA gene from strain RL-C<sup>T</sup> were sequenced and compared with other relative sequences in the GenBank and SILVA rRNA Databases Project libraries (http://www.arb-silva.de/). Phylogenetic analysis based on the 16S rRNA gene sequence showed that strain RL-C<sup>T</sup> belonged to the uncultured Blvi28 wastewater-sludge group (http://www.arb-silva.de/) in the family Rikenellaceae of the phylum Bacteroidetes (Fig. 2). The closest relatives to strain RL-C<sup>T</sup> were environmental clones, such as paddy soil clone 4-CP-Fe-OTU2 (99.1 %, 16S rRNA gene sequence similarity), eutrophic bay clone C-99 (98.3 %), clone RB016 from rhizosphere of Phragmites (98.1 %) and clones from anaerobic granule sludge treating wastewater. In the family Rikenellaceae, the most closely related cultured and characterized micro-organisms were Alistipes shahii (81.8 %), Rikenella microfusus (81.7 %) and Anaerocella delicata (80.9 %) (Song et al., 2006; Kaneuchi & Mitsuoka, 1978; Abe et al., 2012). Several species in the families Porphyromonadaceae, Marinilabiliaceae and Bacteroidaceae in the class Bacteroidia followed at almost the same similarities (e.g. species of the genus Parabacteroides, 81.5–83.1 %; species of the genus Barnesiella, 82.5–83.0 %; Clostridium insidiositesskii, 82.9 %; Bacteroides cellsulosilyticus, 81.0 %). Given the sequence similarity values for the 16S rRNA genes of strain RL-C<sup>T</sup> and related genera were less than 83 %, we propose the creation of a novel genus and species to accommodate strain RL-C<sup>T</sup>.

Comparative phenotypic traits of strain RL-C<sup>T</sup> and related genera Rikenella, Alistipes and Anaerocella in the family Rikenellaceae are shown in Table 1. Strain RL-C<sup>T</sup> shares several common phenotypic traits with related organisms in the same family, such as mesophilic, rod morphology, strictly anaerobic growth and fermentative metabolism. Strain RL-C<sup>T</sup> differed from the related organisms by substrates range, fermentation products and isolation sources. Strain RL-C<sup>T</sup> showed a similar carbohydrate utilization pattern to the genera Rikenella and Alistipes, whereas their fermentation products were differentiated. Species of the genera Rikenella and Alistipes ferment carbohydrates to
complex organic acids, such as acetic, propionic, butyric, isovaleric and succinic acids, while strain RL-C\textsuperscript{T} converted carbohydrates to acetate, \( \text{H}_2 \) and \( \text{CO}_2 \) (Krieg et al., 2010). Strain RL-C\textsuperscript{T} could grow on both carbohydrates and protein compounds, such as tryptone and yeast extract, however, \textit{Anaerocella delicata} can only use proteins but not carbohydrates (Abe et al., 2012). Strain RL-C\textsuperscript{T} was isolated from a reed swamp, whereas species of the genus \textit{Alistipes} have been isolated from various human clinical specimens (Krieg et al., 2010), strains of \textit{Rikenella microfusus} were isolated from faecal or caecal specimens (Kaneuchi & Mitsuoka, 1978), and \textit{Anaerocella delicata} was isolated from a methanogenic reactor (Abe et al., 2012).

On the basis of the phylogenetic, genetic, and physiological properties, it is evident that strain RL-C\textsuperscript{T} represents a novel species of a new genus in the family \textit{Rikenellaceae}, for which the name \textit{Acetobacteroides hydrogenigenes} gen. nov., sp. nov. is proposed.

**Description of \textit{Acetobacteroides} gen. nov.**

\textit{Acetobacteroides} [A.ce.to.bac.te.ro’i.des. L. n. \textit{acetum} vinegar; N.L. n. \textit{bacter} a rod; L. suff. -\textit{oides} (from Gr. suff.-\textit{eidos}, from Gr. \textit{n. eidos} that which is seen, form, shape, figure), resembling, similar; N.L. masc. n. \textit{Acetobacteroides} a rod-shaped micro-organism producing acetic acid].

Strictly anaerobic, Gram-stain-negative, non-motile, straight rods. Non-spor-forming. Chemo-organotrophs. Utilizes some carbohydrates for growth. Oxygen, nitrate, sulfate, sulfite, thiosulfate, elemental sulfur, and Fe(III) nitrotriocerate do not serve as electron acceptors for growth. The genus is a member of the family \textit{Rikenellaceae}.

The type species is \textit{Acetobacteroides hydrogenigenes}.

**Description of \textit{Acetobacteroides hydrogenigenes} sp. nov.**

\textit{Acetobacteroides hydrogenigenes} (hy.dro.ge.ni’ge.nes. N.L. neut. n. \textit{hydrogenum} hydrogen; Gr. \textit{genai}̄ produce; N.L. part. adj. \textit{hydrogenigenes} hydrogen-producing, referring to the metabolic property of the species).

Exhibits the following properties in addition to those given in the genus description. Cells are 0.7–1.0 \textmu m in length. Colonies on agar are light-brown and circular shaped after cultivation at 37 °C for one week.

**Fig. 2.** 16S rRNA gene-based neighbour-joining tree showing the phylogenetic position of strain RL-C\textsuperscript{T} among the order \textit{Bacteroidales}. The sequence of \textit{Clostridium straminisolvens} DSM 16021\textsuperscript{T} (GenBank accession no. AB125279) was used to root the tree (not shown). Bootstrap values >50\% from 1000 resamplings are shown at nodes. Bar, 0.05 nt substitutions per site.

*The major end products by all strains are from glucose fermentation, except *Anaerocella delicata* WN081^T from peptone/yeast extract/vitamins medium.

Grows at 25–40 °C (optimum 37 °C), at pH 5.7–8.0 (optimum pH 7.0–7.5) and in the presence of 0–1.5 % (w/v) NaCl. Ferments yeast extract, tryptone, arabinose, glucose, galactose, mannose, maltose, lactose, glycogen, pectin and starch. Xylan is weakly fermented. Yeast extract is not required for growth, however it stimulates growth slightly. Fermentation products of glucose are acetate, H_{2} and CO_{2}. Does not utilize xylose, ribose, fructose, sucrose, cellobiose, melezitose, melibiose, raffinose, salicin, amygdalin, inulin, cellulose, inositol, mannitol, sodium CM-cellulose, Casamino acids, glutamate, serine, alanine, formate, H_{2}/CO_{2} (1 atm, 80/20, v/v) plus acetate, propionate, butyrate, iso-butyrate, lactate, pyruvate, crotonate, succinate, malate, fumarate, glycerol, ethylene glycol, methanol, ethanol, 1-propanol, 1-butanol, benzoate, hydroquinone or phenol. Cells are catalase-negative. Aesculin and gelatin are not hydrolysed. Indole and H_{2}S are produced from yeast extract. The main fatty acids are iso-C_{15:0}, anteiso-C_{15:0} and C_{16:0}. The most abundant polar lipid is phosphatidylethanolamine.

The type strain is RL-C^T (=JCM 17603^T=DSM 24657^T=CGMCC 1.5173^T), isolated from a reed swamp in China. The genomic DNA G+C content of the type strain is 51.2 mol%.

Dear Authors,

Please find enclosed a proof of your article for checking.

When reading through your proof, please check carefully authors’ names, scientific data, data in tables, any mathematics and the accuracy of references. Please do not make any unnecessary changes at this stage. All necessary corrections should be marked on the proof at the place where the correction is to be made; please mark up the correction in the PDF and return it to us (see instructions on marking proofs in Adobe Reader).

Any queries that have arisen during preparation of your paper for publication are listed below and indicated on the proof.

Please provide your answers when returning your proof.

Please return your proof by email (sgmprod@charlesworth-group.com) within 2 days of receipt of this message.

Ordering reprints for SGM journals

As a result of declining reprint orders and feedback from many authors who tell us they have no use for reprints, **SGM no longer provides free reprints to corresponding authors**; instead, corresponding authors will receive two emails:

i) An email including a link to download the published PDF of their paper. You can forward this link to co-authors or others, and they can also use it to download the published PDF. The link can be used up to 25 times. This email will be sent out at around the time your article is published online.

ii) An email including a link to the SGM Reprint Service. You can forward this email to your co-authors if you wish, so that they can order their own reprints directly, or to your finance or purchasing department, if orders are placed centrally. This email will be sent out at around the time that your article is finalized for printing.

When you click on the link in this second email, you will be taken to an order page to place your reprint order. Like most online ordering sites, it is necessary to set up an account and provide a delivery address while placing your order, if you do not already have an account. Once an account and delivery address have been set up, these details will be stored by the system for use with future orders. Payments can be made by credit card, PayPal or purchase order.

As reprint orders are despatched by courier, there is a charge for postage and packing.
