Supporting Information

ABSTRACT: A Cu\textsuperscript{+}-CP based on the tetranuclear unit \{[[HSQPA]\textsubscript{2}Cu\textsubscript{2}(bipy)\textsubscript{4}] \textsubscript{2}H\textsubscript{2}O\textsubscript{2}\}\textsubscript{2}nH\textsubscript{2}O has been constructed through Cu\textsuperscript{2+} salt, 2-(sulfonylquinilium-8-yloxy)-phthalic acid (H\textsubscript{3}SQPA), and 4,4’-bipyridine (bipy). This Cu\textsuperscript{+}-CP combined with 2,2,6,6-tetramethylpiperidine-1-oxyl as the cocatalyst is an effective catalyst for aerobic oxidation of alcohols and the synthesis of benzoxazoles and can be recycled at least four times without losing its catalytic activity.

The oxidation of alcohols to the corresponding carbonyl compounds is one of the most important reactions in organic synthesis, and extensive efforts have been focused on the development of metal-catalyzed aerobic oxidation methods.\textsuperscript{1} It traditionally requires numerous stoichiometric oxidants and expensive metal catalysts such as palladium and ruthenium.\textsuperscript{2} Copper compounds are well established among the known alcohol oxidation catalysts;\textsuperscript{3} those employing 2,2,6,6-tetramethylpiperidine-1-oxyl (TEMPO) as a redox-active cocatalyst were particularly effective for the aerobic oxidation of alcohols and exhibited broad utilities in both academe and industry.\textsuperscript{4} In contrast to the great development of homogeneous copper-based catalysts, only two supported copper catalysts have been reported,\textsuperscript{5} and heterogeneous copper catalyst systems are still largely unexplored.

On the other hand, coordination polymers and metal–organic frameworks (MOFs) have emerged as a new class of attractive functional materials with considerable promise in catalysis.\textsuperscript{6} These heterogeneous catalysts can be readily recovered and reused while possessing spatially separated single catalytic active sites in their frameworks, which is highly desirable for cost and sustainability considerations. Some mononuclear copper complexes with N,N and N,O ligands in conjunction with TEMPO were found to be efficient catalysts for the aerobic oxidation of alcohols.\textsuperscript{7} However, only four examples of Cu\textsuperscript{2+}-MOF derived from tricarbonylic ligands\textsuperscript{8} and 4,7-bis(4-pyridyl)-1,1,3,3-tetramethylisoindolin-2-yloxy\textsuperscript{9} have been reported to be effective catalysts for the aerobic oxidation of alcohols, and these catalyst systems require an oxygen atmosphere or tert-butyl nitrite. To our best of knowledge, there are presently no reports concerning a Cu\textsuperscript{+}-MOF/CP catalyst system for the aerobic oxidation of alcohols. Our recent works on Pd/Cu-cocatalyzed aerobic alcohol oxidation and the synthesis of CPs\textsuperscript{10} prompted us to explore the possibility of Cu\textsuperscript{+}-CP as a reusable catalyst in the aerobic oxidation of alcohols. Herein, we report the synthesis and structural characterization of six-coordinated Cu\textsuperscript{II} complex 1 and four-coordinated Cu\textsuperscript{I} complex 2 and present an effective procedure for the aerobic oxidation of primary and secondary alcohols to the aldehydes, ketones, and benzoxazoles using a reusable heterogeneous Cu\textsuperscript{+}-CP 2/TEMPO catalytic system under an air atmosphere.

The Cu\textsuperscript{2+}-CP 1, \{[[Cu\textsubscript{2}(SQPA)\textsubscript{2}] \textsubscript{2}H\textsubscript{2}O\textsubscript{2}\} \textsubscript{2}nH\textsubscript{2}O, was obtained by mixing the ligand 2-(sulfonylquinilium-8-yloxy)-phthalic acid (H\textsubscript{3}SQPA) and copper(II) acetate under solvothermal conditions. The asymmetric unit of 1 is simply composed of one Cu\textsuperscript{II} center supported by HSQPA ligands and two coordination molecules, as well as one lattice water molecule, as shown in Figure S2a in the Supporting Information (SI). The two head-to-tail arrangements of the HSQPA ligands adopt the same chelating modes, which link the Cu\textsuperscript{II} centers to generate a dimer unit with a metal—metal distance of 8.49 Å. These units are further extended by an O atom of the sulfonic group to form a railway-like double-chain aggregate (Figure 1).

The Cu\textsuperscript{+}-CP 2 was prepared in high yield by mixing ligands H\textsubscript{3}SQPA and bipy and copper(II) acetate under solvothermal conditions. Interestingly, the Cu\textsuperscript{II} ions were reduced to Cu\textsuperscript{I} ions by in situ reaction owing to the reducibility of the bipy moiety at high temperature.\textsuperscript{11} Single-crystal X-ray diffraction (XRD) analysis reveals that 2 crystallizes in a triclinic system. The asymmetric unit of 2 is composed of two types of Cu\textsuperscript{II} ions, two bipy molecules, two deprotonated (–SO\textsubscript{3}H and –COOH)
HSQPA ligands, and two coordinated and one lattice water molecules (Figure S2b in the SI). Both Cu$^{+}$ ions exhibit a four-coordinated tetrahedral environment with a N$_2$O$_2$ donor set provided by HSQPA, bipy linker moieties, and the coordinated water. Four adjacent Cu$^{+}$ ions form a tetranuclear cluster through a O/N linker. These units are further interconnected by bipy ligands, resulting in a 2D layer, as shown in Figure 2a. The Cu$^{+}$ ion is coordinated to one HSQPA and two bipy ligands through C−O/N bonds, while the CuI and HSQPA ligand link four moieties. CuI, Cu$_2$, and HSQPA ligand can be regarded as 3 and 4-connected nodes, topologically, and the layer can be reduced to a (3,4)-connected network with a Schl"{a}fli symbol of (4.6.8)$^2$ (Figure 2b).

Thermogravimetric/differential thermal analysis (Figure S3 in the SI) indicates that a dehydrate of 2 can be kept intact beyond 300 °C, followed by expulsion of organic components. In order to confirm the oxidation states of the Cu ion, magnetic susceptibility and X-ray photoelectron spectroscopy measurements were performed. The former indicates that 2 is just a diamagnetic material (Figure S4 in the SI). The spin−orbit components ($2p_{3/2}$ and $2p_{1/2}$) of the Cu 2p peak were well deconvoluted by two curves at approximately 932.2 and 952.1 eV with a spin−orbit separation of 19.9 eV (Figure S5 in the SI), confirming the presence of a monovalent oxidation state of Cu$^{+}$ in 2. The pure 2 was confirmed by powder XRD measurement, in which diffraction peaks of experimental data are in agreement with the simulated data from single-crystal X-ray crystallography (Figure S6 in the SI).

Initially, the oxidation of benzylic alcohol was chosen as a model reaction to optimize the reaction conditions under an air atmosphere (Table S3 in the SI). A blank reaction was carried out with KOH as the base in CH$_3$CN; negligible product benzaldehyde was attained. An additional blank experiment was performed under similar conditions using 2 mol % Cu$^{+}$-CP; the isolated yield of benzaldehyde was only 28% (entry 1). However, the yield was greatly improved by the addition of TEMPO (70%, entry 2). The Cu$^{+}$-CP assisted by TEMPO, we performed aerobic oxidation of various alcohols (Table 1). The electronic nature of the substituents on the benzylic alcohol did have an effect on the reaction. Electron-donating substrates reacted to give the products 3a and 3b, and the yields (93 and 88%) are obviously higher than the yields of electron-withdrawing substrates. The oxidation of heterocyclic alcohols proceeded smoothly to provide the desired products 3g−3i in moderate yield (64−73%). In the case of aliphatic alcohol, the product 3j−3l yields (60−76%) were lower than those of the benzylic alcohols. It was noteworthy that the aerobic oxidation of secondary alcohols also gave the expected products 3m−3o in good yield (83−89%) only using Cu$^{+}$-CP in the absence of TEMPO, while the oxidation of 1-phenylethanol catalyzed by Cu$_3$(BTC)$_3$/TEMPO gave the product 3n with only a very low yield (14%).

Promoted by the good results obtained in the aerobic oxidation of alcohols catalyzed by Cu$^{+}$-CP, we explored whether this catalytic system would allow the preparation of 2-arylbenzoxazoles from benzylic alcohols. The results obtained are summarized in Table 2. To our delight, under the same conditions, benzy alcohol and 2-aminophenol were converted to the 2-phenylbenzoxazole 4a (82%). Subsequently, the reactions of 2-aminophenol with benzylic alcohols bearing methyl and methoxy groups were investigated, and good yields were obtained (85 and 86%). In contrast to 2-monoarylbenezoxazoles, only the two examples of 2-biarylbenzoxazoles 4d and 4e have been reported. To broaden the substrate scope, we further investigated 2-aminophenol with a variety of electronic and functional groups. The reusability of Cu$^{+}$-CP 2 was investigated for the oxidations of benzyl alcohol and 4-methylbenzyl alcohol under the optimized conditions as described in Table S4 in the SI. It was observed that the Cu$^{+}$-CP catalyst could be recycled and reused four times without any loss of activity. The XRD pattern of the recovered CP further confirmed its recyclability (Figure S7 in the SI). As can be seen, there are only minor changes in the relative intensities of some peaks. This may be because TEMPO will coordinate with the active sites of CP. Additionally, the catalyst could retain the integrity of its molecular structure, as evidenced by Fourier transform infrared (Figure S8 in the SI).

The electronic nature of the substituents on the benzaldehyde is shown in Figure 2b. A 6-membered short circuit is highlighted in red, and the rod passing through it is highlighted in green (orange nodes are for Cu$^{+}$ centers and blue nodes for H$_3$SQPA ligands).

“Structural biarylmethanols. The corresponding 2-biarylbenzoxazoles 4f–4k were isolated in moderate-to-good yields (61–81%). Finally, this protocol was found also to proceed successfully with 4-heteroarylbenzyl alcohols, furnishing moderate yields (64–76%). The detailed structure of 4h was confirmed by single-crystal X-ray crystallography (Figure S2c in the SI).

In summary, we have synthesized two coordination polymers containing the dinuclear Cu\(^{3+}\) and tetranuclear Cu\(^{2+}\) units. The latter cuprocupric CP combined with TEMPO shows surprising catalytic performance in the aerobic oxidation of primary and secondary alcohols under an air atmosphere. It is easy to synthesize and can be recycled and reused for four runs without any significant loss of catalytic activity. Moreover, this catalytic system has been successfully applied to the synthesis of 2-arylbenezoxazoles from benzyl alcohols and 2-aminophenol.
