**Background:** The primary function of the abundant and highly conserved protein TCTP is not clear.

**Results:** TCTP binds to a conserved central acidic region of eukaryotic elongation factor 1Bα/β/δ.

**Conclusion:** The binding of TCTP to eukaryotic elongation factor 1B is evolutionarily conserved.

**Significance:** The interaction with eEF1B represents a primary function of TCTP.

Translationally controlled tumor protein (TCTP) is an abundant protein that is highly conserved in eukaryotes. However, its primary function is still not clear. Human TCTP interacts with the metazoan-specific eukaryotic elongation factor 1Bδ (eEF1Bδ) and inhibits its guanine nucleotide exchange factor (GEF) activity, but the structural mechanism remains unknown. The interaction between TCTP and eEF1Bδ was investigated by NMR titration, structure determination, paramagnetic relaxation enhancement, site-directed mutagenesis, isothermal titration calorimetry, and HADDOCK docking. We first demonstrated that the catalytic GEF domain of eEF1Bδ is not responsible for binding to TCTP but rather a previously unnoticed central acidic region (CAR) domain in eEF1Bδ. The mutagenesis data and the structural model of the TCTP-eEF1Bδ CAR domain complex revealed the key binding residues. These residues are highly conserved in eukaryotic TCTPs and in eEF1B GEFs, including the eukaryotically conserved eEF1Bα, implying the interaction may be conserved in all eukaryotes. Interactions were confirmed between TCTP and the eEF1Bα CAR domain for human, fission yeast, and unicellular photosynthetic microalgal proteins, suggesting that involvement in protein translation through the conserved interaction with eEF1B represents a primary function of TCTP.

Translational control of protein (TCTP), also named fortilin, histamine release factor, and p23, is a 20–25-kDa, highly conserved, and abundantly and ubiquitously expressed protein with growth- and immunity-related functions in eukaryotic cells (1–8). TCTP participates in these physiological functions via interactions with a large number of different proteins. However, many of these functions presumably only occur in limited species because the corresponding TCTP-binding partners are not well conserved in eukaryotes. For example, it was demonstrated recently that TCTP directly interacts with p53 forming a negative feedback loop (9); but p53 does not exist in plants and lower eukaryotes, although TCTP is conserved. Therefore, this function, although important in humans, clearly does not represent the primary cellular function of TCTP. Among the TCTP functions reported in the literature, one candidate for the primary function of TCTP is its involvement in protein translation by interaction with the eukaryotic elongation factor 1 (eEF1) complex (10–12), because the eEF1 complex is conserved in all eukaryotes.

The eukaryotic elongation factor 1 (eEF1) complex is responsible for transporting the aminoacyl tRNA to the ribosome during protein synthesis (13, 14). The complex consists of a G-protein named eEF1A responsible for delivering the aminoacyl tRNA to the ribosome in its GTP-bound active state, and a guanine nucleotide exchange factor (GEF) complex named eEF1B (Fig. 1). The eEF1B complex is composed of one or two GEFs (eEF1Bα exists in all eukaryotes, eEF1Bδ exists only in metazoans, and eEF1Bβ exists only in plants), a scaffold component named eEF1Bγ, and a valine-tRNA synthetase additional in metazoans. All GEFs in eEF1B share a highly conserved C-terminal catalytic GEF domain, although their N-terminal domains are less conserved and are responsible for binding with other eEF1B components (13, 14). The structures of the catalytic domain of human eEF1Bα and the yeast eEF1A-eEF1Bα complex have been reported (15–17), which reveals that a C-terminal lysine residue is the key residue for releasing GDP from eEF1A. Sequence analysis indicated that eEF1Bδ contains paramagnetic relaxation enhancement; MTSL, 1-oxyl-2,2,5,5-tetramethyl-Δ3-pyrroline-3-methyl methanethiosulfonate; CSP, chemical shift perturbation; HSQC, heteronuclear single quantum coherence.
three domains as follows: the N-terminal domain (residues 1–153), the central acidic region (CAR) domain (residues 153–192) (pfam10587 in PFAM database), and the C-terminal catalytic GEF domain (residues 192–281). Previous studies indicate that TCTP physically interacts with the C-terminal region (CAR-GEF region; residues 153–281) of eEF1Bδ and inhibits its GEF activity (10, 11).

Although the three-dimensional structures of TCTP homologues from different species have been solved and are shown to be highly conserved (6, 18–22), there are few reports giving structural information regarding the interaction of TCTP with its partner proteins. Furthermore, as indicated by Bommer and Thiele (5), additional very careful work is required to establish the complete array of molecular interactions of TCTP because TCTP frequently appears as an “interacting protein” in two-hybrid screens. Here, by employing various structural techniques, including NMR titration, chemical shift mapping, paramagnetic relaxation enhancement, and HADDOCK docking, as well as isothermal titration calorimetry (ITC) and site-directed mutagenesis, we identified the binding interfaces and key residues in the interaction between TCTP and eEF1Bδ. We found that TCTP unexpectedly binds to the previously unnoticed CAR domain (residues 153–192), instead of the C-terminal catalytic GEF domain of eEF1Bδ. The CAR domain is conserved in all eEF1B GEFs and is structurally independent from the GEF domain. The key residues for the interaction identified in TCTP are highly conserved in eukaryotes, and those in eEF1Bδ are conserved not only in metazoan eEF1Bδ but also in eEF1Bα as well as plant eEF1Bβ, suggesting a conserved interaction between TCTP and eEF1B GEFs. The interaction between eEF1Bα and TCTP of human, fission yeast, and unicellular photosynthetic microalgae was further confirmed, which demonstrates that the interaction of TCTP and the eEF1 complex is conserved in eukaryotes. The results in this study imply that involvement in protein translation is one of the primary cellular functions of TCTP.

EXPERIMENTAL PROCEDURES

Protein Expression and Purification—The gene of full-length human eEF1Bδ was cloned into the pGEX-6P-1 expression vector. The recombinant eEF1Bδ protein containing an N-terminal GST tag was expressed in Escherichia coli BL21 (DE3). Cells were grown at 37 °C, and the protein expression was induced for 3 h with 0.4 mM isopropyl β-D-thiogalactopyranoside when the absorbance at 600 nm reached 0.7–0.8. The cells were harvested by centrifugation at 4800 × g at 4 °C for 30 min. The cell pellets were resuspended in buffer A (20 mM Tris-HCl, pH 7.5, 200 mM NaCl) and stored at −20 °C overnight. After cell lysis by thawing and ultrasonication, the lysate was centrifuged, and the supernatant was applied onto a GST column (GE Healthcare) and washed with buffer B (140 mM NaCl, 2.7 mM KCl, 10 mM Na2HPO4, 1.8 mM KH2PO4, 2.0 mM urea, pH 7.2). The proteins were eluted with buffer C (50 mM Tris-HCl, pH 8.0, 500 mM NaCl) containing 10 mM reduced glutathione and 1 mM DTT. After that, the protein was purified by gel filtration chromatography using a Superdex G200 column (GE Healthcare), with buffer C containing 1 mM urea to avoid severe aggregation. During the whole purification process, protease inhibitor mixture (Calbiochem) was added according to the manual, and all experiments were carried out at low temperature.

The N-terminal domain (residues 1–153), CAR domain (residues 153–192), catalytic GEF domain (residues 192–281), and a fragment containing the CAR domain plus GEF domain (CAR-GEF region; residues 153–281) of human eEF1Bδ were cloned into a modified PET28a expression vector, with a His-tagged GB1 domain followed by a PreScission protease cleavage site at the N terminus. All eEF1Bδ domains (except the N-terminal domain) were purified by a similar protocol. The proteins were first purified using a Ni2⁺ column (chelating Sepharose Fast Flow), and then were digested with PreScission protease. The digested product was applied onto the Ni2⁺ column again. Flow-through solutions containing desired proteins were collected, concentrated, and further purified by gel filtration chromatography using a Superdex 75 column (GE Healthcare). The eEF1Bδ N-terminal domain was expressed mainly in inclusion bodies, and the yield purified from the supernatant was quite low. To purify sufficient eEF1Bδ N-terminal domain, 8 M urea was added into buffer A to resuspend the inclusion bodies. After Ni2⁺-affinity purification, the eluted fraction was dialyzed to remove urea and imidazole, then concentrated, and further purified by gel filtration. Circular dichroism spectroscopy was used to confirm its refolding (as for proteins purified from the supernatant). The purified protein was collected and digested with 2 mg of PreScission protease, and then a Ni2⁺ column was used again to separate eEF1Bδ N-terminal domain from GB1 domain.

The human eEF1Bα CAR domain (residues 97–136) and the CAR-GEF region (residues 97–225) were cloned into a modified pET28a expression vector, with a His-tagged SMT3 protein in the N terminus instead of the GB1 domain. These domains were purified by a protocol similar to that in the previous paragraph, except that the His-tagged SMT3 protein was removed by digestion with ULP1 protease.
Conserved Interaction between TCTP and eEF1B

Wild-type human TCTP was expressed and purified as reported previously (6). The construction of different mutants of the eEF1Bβ CAR domain and TCTP (except the TCTP mutants for paramagnetic relaxation enhancement (PRE) experiments) was carried out by the QuikChange method (23). After PCR with mutagenic primers, DpnI was added to digest the methylated unmaturated parental template. The product was transformed into E. coli TOP10 competent cells. The purification of mutant proteins was similar to that of the wild-type proteins. For the TCTP mutants used in PRE experiments, including C172S, C28S/C172S, C28S/C172S/T116C, C28S/C172S/A127C, and C28S/C172S/D143C, the coding sequence of mutant TCTP was cloned into pET11a or pET30a expression vector without any tag. After expression in E. coli BL21(DE3), the cells were resuspended in buffer A without NaCl. After cell lysis and centrifugation, the lysate was loaded onto a DEAE column. The mutant TCTP was eluted with 150 mM NaCl. The eluate was dialyzed to remove NaCl followed by Q-Sepharose high performance column (GE Healthcare) purification. The mutant TCTP was eluted with a gradient of NaCl concentrations from 50 to 300 mM. The eluate was concentrated and further purified using a Superdex 75 gel filtration column.

TCTP, eEF1Be CAR domain, and the CAR-GEF region from fission yeast Schizosaccharomyces pombe and photosynthetic microalga Nannochloropsis oceanica IMET1 were cloned into pET30a for protein expression. The same procedure was used for expression and purification of these two proteins. The plasmid was transformed into E. coli BL21(DE3). Cells were grown at 37 °C, and the protein expression was induced for 5 h with 0.5 mM isopropyl β-D-thiogalactopyranoside when the absorbance at 600 nm reached 1.0. The proteins were first purified using a Ni²⁺ column (chelating Sepharose Fast Flow) and further purified by gel filtration chromatography using a Superdex 75 column (GE Healthcare). The buffer for gel filtration and final protein storage was 50 mM sodium phosphate buffer, pH 7.0, containing 200 mM KCl, 5 mM DTT, and 5 mM EDTA.

Peptides EDDDDIDLFGSNDNE, DLFGS, and LFG were synthesized by Sangon Biotech (Shanghai, China). ¹⁵N- and ¹⁵N/¹³C-labeled proteins were prepared using the same procedures except cells were grown in M9 minimal media containing ¹⁵NH₄Cl and [¹³C]glucose as the sole nitrogen and carbon sources, respectively.

NMR Spectroscopy—NMR experiments were performed on 298 K on Bruker DMX, AVANCE, and Agilent DD2 600 MHz NMR spectrometers equipped with cryo-probes. All NMR samples contained 0.2–0.8 mM ¹⁵N- or ¹⁵N/¹³C-labeled protein in 20 mM Tris-HCl, pH 7.5, 200 mM NaCl, 0.01% 2,2-dimethyl-2-silapentane-5-sulfonate, and 10% (v/v) D₂O.

Two-dimensional ¹H-¹⁵N and ¹H-¹³C HSQC and three-dimensional CBCA(CO)NH, HNCA, HNCC, HN(CA)CO, HBHA(CO)NH, HBHANH, HCCD-TOSY, CCH-COSY, and CCH-TOCSY experiments were performed for backbone and side chain assignments of the eEF1Bβ CAR domain in free and TCTP-bound states. Three-dimensional ¹H-¹⁵N and ¹H-¹³C NOESY-HSQC spectra with mixing times of 300 ms were collected to generate distance restraints. All data were processed with FELIX (Accelrys Inc.) or NMRPipe (24) and analyzed with NMRViewJ (25).

Heteronuclear steady-state ¹H-¹⁵N NOE experiments and CLEANEX-PM experiments (26) were performed using standard pulse programs. Samples of ¹⁵N-labeled human eEF1Bβ CAR-GEF region in free and TCTP-bound states were used in the experiments. The mixing times for CLEANEX-PM experiments ranged from 5 to 500 ms, and the data acquired using short mixing times (5, 10, 15 and 20 ms) were used to estimate the amide-water exchange rates.

Paramagnetic Relaxation Enhancement Experiments—PRE experiments were performed using proteins labeled with 1-oxyl-2,2,5,5-tetramethyl-Δ3-pyrroline-3-methyl methanethiosulfonate (MTSL) (Toronto Research Chemicals, Toronto, Canada) on one free cysteine. Native cysteines on the surface of proteins were mutated to serine to avoid undesired MTS labeling. The eEF1Bβ CAR domain contains no cysteines, whereas TCTP contains two cysteines, Cys-28p and Cys-172p. (The residues and the mutants of human eEF1Bβ and TCTP are designated by a subscripts suffix δ and p for eEF1Bδ and TCTP, respectively, e.g. Pro-150 of eEF1Bδ will be represented as Pro-150δ, and the C172S mutant of TCTP will be represented as C172Sp.) Because the two cysteines are far away from the binding surface, the C28S/C172S double mutant of TCTP was used in the PRE experiments without interfering with the interaction. Different TCTP or eEF1Bδ cysteine mutants were incubated with MTSL for 16 h at 25 °C in nonreducing buffer, and excess MTSL was removed by dialysis against 20 mM Tris-HCl buffer, pH 7.5, 200 mM NaCl for 6 h at 4 °C. Spin-labeled protein was added to other ¹⁵N-labeled protein for NMR experiments. The reduced compound was generated by incubation with 1.5 mM ascorbic acid for 1 h at 25 °C. The two-dimensional ¹H-¹⁵N HSQC spectra of ¹⁵N-labeled proteins were acquired at a 1:1 molar ratio in the oxidized and reduced states (27).

Structural Calculations—The structures of the eEF1Bδ CAR domain in the free and TCTP-bound states were initially calculated with the program CYANA (28), and then refined using CNS (29) and RECOORDScript (30) in explicit water with manual assignments. Backbone dihedral angle restraints obtained using TALOS (31) and hydrogen bond restraints of the α-helix were also incorporated into the structural calculation in the later stages of refinement. From 100 initial structures, 50 lowest energy conformers were selected for refinement in explicit water, and the 20 lowest energy conformers represent the final ensemble of structures. The quality of the structural analysis and related statistics were obtained using the programs MOLMOL (32) and PROCHECK-NMR (33). The structures have been deposited in the Protein Data Bank with accession codes 2MVN and 2MVM for the eEF1Bδ CAR domain in free and TCTP-bound states, respectively.

HADDOCK Docking—The structure of the TCTP-eEF1Bδ CAR domain complex was calculated on the HADDOCK webserver (34). The x-ray structure of TCTP (Protein Data Bank code 1Y2Z) and NMR structure of TCTP-bound eEF1Bδ CAR domain were used as the starting structures. The CSP data were used to construct the ambiguous constraints of the binding surface. PRE and mutagenesis constraints were used as unambiguous constraints. PRE constraints were derived from the PRE data of MTSL-labeled T116Cp, A127Cp, D143Cp, K169Cp, E177Cp, and K186Cp. Mutagenesis constraints were set up for...
residues whose mutation caused significant changes in the binding (site I, Ile-92\textsubscript{p}, Met-96\textsubscript{p}, Met-115\textsubscript{p}, Ala-118\textsubscript{p}, Ile-122\textsubscript{p}, Leu-159\textsubscript{p}, and Phe-160\textsubscript{p}; site II, Phe-83\textsubscript{p}, Met-140\textsubscript{p}, and Tyr-182\textsubscript{p}). During the calculation, residues 155–165 of eEF1B were set to be fully flexible.

NMR Titration Experiments—The concentration of \textsuperscript{15}N-labeled proteins in all titration experiments was 0.1–0.3 mM. The concentration of stock solution of ligands was 1–5 mM in the same buffer. All experiments were performed at 25 °C in 20 mM Tris-HCl buffer, pH 7.5, 200 mM NaCl, except for the high salt experiment which contained 400 mM NaCl. The values of chemical shift perturbations (CSP) were calculated using Equation 1,

\[
\text{CSP} = \sqrt{\Delta \text{HN}^2 + 0.2 (\Delta \text{N})^2} \quad (\text{Eq. 1})
\]

where \(\Delta \text{HN}\) and \(\Delta \text{N}\) are the changes in \(^1\text{HN}\) and \(^{15}\text{N}\) chemical shifts, respectively.

The equilibrium dissociation constants \(K_r\) were estimated by fitting the observed CSPs Equation 2

\[
\text{CSP} = \frac{\text{CSP}_{\text{max}}}{2} \left( 1 + r + K_d \left( \frac{1}{C_{\text{pro}}} + \frac{r}{C_{\text{lig}}} \right) \right) - \left( 1 + r + K_d \left( \frac{1}{C_{\text{pro}}} + \frac{r}{C_{\text{lig}}} \right) \right)^2 - 4r \quad (\text{Eq. 2})
\]

where \(\text{CSP}_{\text{max}}\) is the CSP at the theoretical saturated condition obtained from the fit; \(r\) is the molar ratio of ligand to protein; \(C_{\text{pro}}\) is the concentration of initial protein solution; and \(C_{\text{lig}}\) is the stock concentration of ligand.

Isothermal Titration Calorimetry—ITC measurements were performed on an iTC-200 calorimeter (MicroCal Inc.). All experiments were performed in 20 mM Tris-HCl buffer, pH 7.5, 200 mM NaCl, except for the high salt experiment which contained 400 mM NaCl. The interval between each injection lasted 150 s. Control experiments were performed under identical conditions to determine the heat signals that arise from addition of the eEF1B\textsubscript{\textalpha} into the buffer. Data were fitted using the single-site binding model within the Origin software package (MicroCal Inc.). To determine the heat capacity change \(\Delta C_p\) ITC experiments were carried out at 10, 15, 20, 25, and 30 °C. The \(\Delta C_p\) value was estimated by linear fitting of the \(\Delta H\) values obtained against temperature.

RESULTS

CAR Domain of eEF1B\textsubscript{\textalpha} Is the Region Responsible for TCTP Binding—The C-terminal region (residues 153–281) containing the CAR and GEF domains of eEF1B\textsubscript{\textalpha} was previously identified as the TCTP binding region (10, 11). However, we found that the CAR domain and the GEF domain are in fact independent structural domains, as the peaks in the \(^1\text{H}-^{15}\text{N}\) HSQC spectrum of the isolated CAR domain overlay well with the corresponding peaks in the \(^1\text{H}-^{15}\text{N}\) HSQC spectrum of the isolated CAR domain overlay well with the corresponding peaks in the \(^1\text{H}-^{15}\text{N}\) HSQC spectrum of the CAR-GEF region (Fig. 2). In the NMR titration of \(^{15}\text{N}\)-labeled TCTP with the eEF1B\textsubscript{\textalpha} CAR-GEF region (Fig. 3A) and isolated CAR domain (Fig. 4A) as well as full-length eEF1B\textsubscript{\textalpha} (data not
shown), almost identical chemical shift perturbations were observed for peaks in the $^1$H-$^15$N HSQC spectra of $^{15}$N-labeled TCTP. Interestingly, no chemical shift perturbations were observed when TCTP was titrated with the GEF domain alone (data not shown). Furthermore, no interaction was observed between the N-terminal domain of eEF1B$\delta$ and TCTP (data not shown). In the reverse titration of the $^{15}$N-labeled CAR-GEF region with TCTP (Fig. 3B), the peaks from the CAR domain in the $^1$H-$^15$N HSQC spectrum showed significant chemical shift perturbations, the same as when the $^{15}$N-labeled isolated CAR domain was titrated with TCTP (Fig. 4B), although the peaks from the GEF domain showed no change during the titration (Fig. 3C). Therefore, this indicates that the CAR domain is the region responsible for TCTP binding.

The equilibrium dissociation constants ($K_D$) between TCTP and the eEF1B$\delta$ CAR domain or the CAR-GEF region estimated by fitting the chemical shift changes during the titration were around 30 $\mu$M (Fig. 4C and Table 1), indicating low-to-medium binding affinity between TCTP and eEF1B$\delta$. ITC experiments showed similar values for the binding affinity of TCTP for the
eIF1Bδ CAR domain or the CAR-GEF region (Fig. 4D and Table 1). Moreover, the thermodynamic parameters obtained from ITC experiments showed that the binding is dominated by the enthalpy change (Table 2), and the heat capacity change of binding obtained from ITC experiments carried out at different temperatures ranging from 10 to 30 °C was $-272 \pm 49$ cal/mol/K, indicating the removal of solvating water molecules upon binding. Based on the above experimental results, we can conclude that the independent CAR domain is the structural region of eIF1Bδ involved in binding to TCTP.

Solution Structure of eEF1β CAR Domain in Free and TCTP-bound States—All peaks in the \(^1\)H–\(^15\)N HSQC spectrum of the eEF1β CAR domain, including the significantly overlapped peaks (Lys-185\(_\beta\), Lys-180\(_\alpha\), and Arg-180\(_\delta\), Glu-176\(_\alpha\), Glu-184\(_\lambda\), and Gln-181\(_\lambda\)), were unambiguously assigned using triple resonance experiments (Fig. 2A). The structure of the eEF1β CAR domain was calculated based on the nearly complete assignments and various restraints (Table 3). The final structure of the eEF1β CAR domain (Fig. 5, A and C) shows an \( \alpha \)-helical structure comprising one helix for residues 169–185 and two flexible loops for the residues of both terminal regions. The steady-state \(^1\)H–\(^15\)N NOE experiment indicated that the \( \alpha \)-helix is a relatively rigid structure indicated by larger NOE values, whereas the flexible loops have smaller NOE values (Fig. 5F). Negatively charged residues are mainly located in the N-terminal loop and the N-terminal part of the \( \alpha \)-helix, whereas positively charged residues are mainly located in the C-terminal loop and the C-terminal part of the \( \alpha \)-helix. Hydrophobic residues are sparsely distributed along the N-terminal loop and the whole \( \alpha \)-helix (Fig. 5C). To probe the structural changes in the eEF1β CAR domain upon TCTP binding, we determined the structure of the eEF1β CAR domain in the TCTP-bound state (Fig. 5, B and D). Comparing the structures of the eEF1β CAR domain in the bound and free states, the helix in the bound state was extended at both the N and C termini (from residues 169–185 to 168–187), and the N-terminal loop becomes more convergent (Fig. 5, B, D, E). The flexible-to-rigid transition in the structure was also revealed by the increased heteronuclear steady-state \(^1\)H–\(^1\)H NOEs of the N-terminal loop and further evidenced by the larger number of observable \(^1\)H–\(^1\)H NOEs available for use in the structural calculation (Fig. 5F and Table 3). This flexible-to-rigid transition upon TCTP binding was further evidenced by CLEANEX-PM experiments of the eEF1β CAR-GEF region, which measured the amide-water hydrogen exchange rates (Fig. 5G). The eEF1β CAR domain showed a significant decrease in the exchange rates upon TCTP binding, whereas the rates of the GEF domain were largely unchanged.

Binding Surfaces on TCTP and eEF1β CAR Domain—The binding surfaces on TCTP and the eEF1β CAR domain were determined by mapping the CSPs onto the protein structures (Fig. 6). Structural regions containing residues with significant CSPs (larger than average value plus 1 S.D.) when TCTP was titrated with the eEF1β CAR domain, and vice versa, were identified as the binding surfaces of the proteins. TCTP contains two binding surfaces as follows: the \( \alpha \)-hairpin region, including helices a2 and a3 of TCTP (TCTP site I), and one side of the \( \beta \)-core (TCTP site II), including loops L\(_{\text{a1b2}}\), L\(_{\text{b3a2}}\), L\(_{\text{b4b5b6b6b7}}\), and strands \( \beta \)1, \( \beta \)2, \( \beta \)8, and \( \beta \)9 (Fig. 6, A and B). TCTP site I contains many positively charged residues surrounding a hydrophobic pocket on the surface (Fig. 6, C and D), and TCTP site II is a hydrophobic patch surrounded by a few negatively charged residues in loop L\(_{\text{b8b9}}\) (Fig. 6C). The eEF1β CAR domain also has two binding surfaces as follows: residues 155–161 in the N-terminal loop (eEF1β site I), and residues 179–188 mainly in the \( \alpha \)-helix (eEF1β site II) (Fig. 6, D and E). EEF1β site I is highly negatively charged (Fig. 6, F and G) with a few hydrophobic residues (Ile-157\(_\beta\), Leu-159\(_\beta\), and Phe-160\(_\beta\)). This site may undergo a significant conformational/environmental change upon binding because residue Phe-160\(_\beta\) showed an extraordinarily high CSP value (Fig. 6D). EEF1β site II contains both hydrophobic and positively charged residues (Fig. 6F). Interestingly, in terms of electrostatic and hydrophobic interactions, eEF1β sites I and II are complementary with TCTP sites I and II, respectively.

Conserved Interaction between TCTP and eEF1B

FIGURE 6. Mapping the binding surfaces of TCTP and eEF1Bδ CAR domain. A, CSPs of TCTP titrated with eEF1Bδ CAR domain (molar ratio 1:2.2). B, structural mapping of CSPs on TCTP. C, electrostatic surface of TCTP. D, CSPs of eEF1Bδ CAR domain titrated with TCTP (molar ratio 1:2.2). E, structural mapping of CSPs on the eEF1Bδ CAR domain. F, electrostatic surface of the eEF1Bδ CAR domain. G, close-up view of electrostatic surfaces of sites I of TCTP (left) and the eEF1Bδ CAR domain (right). A and D, solid and dashed lines represent the average value and average value plus 1 S.D. of total CSPs, respectively; the blue single and doubles lines on the top indicate the binding sites I and II of each protein, respectively; secondary structure elements are shown on the top. B and E, residues with a CSP value more than the average value plus 1 S.D. are shown in red; those with a CSP value between the average value and average value plus 1 S.D. are shown in pink. Unassigned residues are shown in black. Residues for MTSL labeling in PRE experiments are shown as green sticks with label. The arrow in C indicates the hydrophobic pocket in site I of TCTP.
**Intermolecular Orientation Probed by PRE**—Because structural determination of the TCTP-eEF1B\(\delta\) complex was not possible because of the weak interaction between TCTP and eEF1B\(\delta\), the following strategy was adopted to obtain the structure of the complex. First, PRE experiments were conducted to obtain the orientation of the two proteins in the complex. Second, the key residues in the interaction were identified by titration of proteins with various single point mutations on the binding surfaces. Third, HADDOCK combined with CSP, PRE, and mutagenesis data was used to calculate the structure of the complex. (The second and third approaches are described in the subsequent sections.)

For PRE experiments, three residues of TCTP (Thr-116\(p\), Ala-127\(p\), and Asp-143\(p\)) were chosen as MTSL-labeling sites to detect interactions with the eEF1B\(\delta\) CAR domain. Thr-116\(p\) and Ala-127\(p\) are located, respectively, at the N- and C-terminal parts of helix\(\alpha3\) around TCTP site I; and Asp-143\(p\) is close to TCTP site II (Figs. 6B and 7B). To further investigate the interactions between the two proteins, five residues of the eEF1B\(\delta\) CAR domain were chosen as MTSL-labeling sites as follows: Pro-150\(\alpha\) and Ala-191\(\alpha\) at the N- and C-termi, respectively, and Lys-169\(\alpha\), Glu-177\(\alpha\), and Lys-186\(\alpha\) in the \(\alpha\)-helix (Figs. 6E and 7A). MTSL-labeled T116C\(p\) caused attenuation of the signals.

---

**FIGURE 7. PRE results of TCTP-eEF1B\(\delta\) CAR domain interaction.** A and B, MTSL-labeling sites of eEF1B\(\delta\) CAR domain (A) and TCTP (B). The side chains of labeled residues are shown as red balls and sticks. C–H, PRE effects and structural mapping on eEF1B\(\delta\) CAR domain by MTSL-labeled TCTP. I–N, PRE effects and structural mapping on TCTP by MTSL-labeled eEF1B\(\delta\) CAR domain. The blue single and doubles lines on the top indicate the binding sites I and II of each protein, respectively. In the structural mapping, the residues with more than 40% peak intensity attenuation were indicated by different colors for different labeling sites. Unassigned residues are shown in black.
**Conserved Interaction between TCTP and eEF1B**

from the eEF1Bδ site I (Fig. 7, C and D), whereas MTSL-labeled A127Cp affected the N-terminal residues in the HSQC spectrum of the eEF1Bδ CAR domain (Fig. 7, E and F). Signals from residues at eEF1Bδ site II were broadened by MTSL-labeled D143Cp (Fig. 7, G and H), whereas MTSL-labeled K169Cδ caused specific signal attenuation for residues from TCTP site I (Fig. 7, I and J). The PRE effect of MTSL labeled E177Cp was observed as signal attenuation of residues located between TCTP sites I and II as well as some residues within the sites (Fig. 7, K and L), whereas MTSL-labeled K186Cq reduced signals from TCTP site II (Fig. 7, M and N). No PRE effect of MTSL-labeled P150Cq and A191Cq was observed (data not shown). These results indicate that eEF1Bδ sites I and II interact with TCTP sites I and II, respectively.

The above PRE data allow a model of the intermolecular orientation to be generated. The N-terminal loop of the eEF1Bδ CAR domain (eEF1Bδ CAR site I) is close to the α-hairpin of TCTP (TCTP site I), whereas the N terminus of the eEF1Bδ CAR domain is toward the C terminus of helix α3 of the α-hairpin of TCTP. The α-helix of the eEF1Bδ CAR domain (eEF1Bδ site II) is close to the β-core of TCTP (TCTP site II), whereas the region connecting eEF1Bδ sites I and II is close to the structural region between the α-hairpin and the β-core of TCTP.

**Key Residues Drive Interaction between TCTP and eEF1Bδ CAR Domain**—According to the above data, electrostatic and/or hydrophobic interactions may drive the binding of the eEF1Bδ CAR domain to TCTP. The question is whether hydrophobic or charged residues play the most important role in the interaction. NMR titration performed with mutant proteins containing various single mutations in the binding site of each protein (Table 4 and Fig. 8) was adopted to identify the key residues for binding in the two proteins.

The hydrophobic pocket of TCTP site I could accommodate the hydrophobic residues of eEF1Bδ site I. Consistent with this, mutants L159Ap, F160Ap, M115Dp, and A118Dp showed no binding with their wild-type binding partner, whereas M96Ap and A119Ep did not change the binding, showing that aromatic or charged residues play the most important role in the interaction. Replacement of phenylalanine with leucine or tyrosine instead of alanine at residue 160 also prevents binding between the two proteins. In addition, mutants I92Ap, M96Np, A119Kp, L122Ap, and I157Ap, as well as G161Kδ, decreased the binding affinity about 3–30-fold. Meanwhile, MTSL-labeled K186Dp, K97Qp, and K123Ep showed severalfold decrease in affinity, whereas mutants A118Dp, M115Kp, D156Kq, S162Kq, and P142Ap showed similar binding values to that of wild type (Table 4). In TCTP site II and eEF1Bδ site II, mutations of hydrophobic residues Y182Aδ, F83Amp, and M140Ap decreased binding affinities by severalfold, whereas L179Ap and P142Aδ showed affinities similar to that of wild type. Analysis of TCTP CSP values caused by Y182Ap and eEF1Bδ CSP values caused by F83Ap and M140Ap revealed that most residues in TCTP site II and eEF1Bδ site II failed to show significant chemical shift changes. Meanwhile, mutations of charged residues K186Dδ and K189Dδ had almost no effect on

**FIGURE 8.** Mutation sites on the structure of human TCTP (A) and the human eEF1Bδ CAR domain (B). The side chains of mutated residues are shown as sticks. Neutral, positively charged, and negatively charged residues are shown in **green**, **blue**, and **red**, respectively.
the interaction. All these data suggest that hydrophobic rather than electrostatic interactions between the binding sites on the two proteins play a crucial role in the binding, and the eEF1Bδ site I is critical for binding with TCTP. However, the binding affinity in 400 mM NaCl decreased about 7-fold compared with that in 200 mM NaCl (30 versus 214 µM) (Table 1). Therefore, hydrophobic interactions dominate the binding between TCTP and the eEF1Bδ CAR domain, whereas electrostatic interactions also contribute to the binding affinity.

To further confirm the importance of eEF1Bδ site I for interaction with TCTP, TCTP was titrated with peptides EDD-DIDLFGSDNE, DLFGS, and LFG corresponding to residues 153–165 (containing all residues of eEF1Bδ site I), 158–162, and 159–161 of the eEF1Bδ CAR domain, respectively. All peptides showed interaction with site I of TCTP, and longer peptides showed stronger affinity (Table 4). Therefore, the two hydrophobic residues Leu-159 and Phe-160 in cooperating with other residues from eEF1Bδ site I play key roles in the binding.

Structural Model of the TCTP-eEF1Bδ CAR Domain Complex—The structural model of the TCTP-eEF1Bδ CAR domain complex was determined by HADDOCK docking computation (34). The structural model obtained demonstrates a large buried interacting surface area (2337.4 ± 87.2 Å²) (Table 5 and Fig. 9A). The two hydrophobic residues Leu-159 and Phe-160 in eEF1Bδ site I insert into the hydrophobic pocket of TCTP site I between the two helices α2 and α3, although surrounding charged residues form salt bridges (Fig. 9B). Tyr-182 of eEF1Bδ site II contacts with two hydrophobic residues Phe-83p and Met-140p of TCTP site II (Fig. 9C). The helix of the eEF1Bδ CAR domain forms 119.6 ± 3.3 and 49.8 ± 2.7° angles with the helices α2 and α3 of TCTP, respectively.

The docking model of the complex of TCTP and the eEF1Bδ CAR domain shows continuous interacting surfaces, including sites I and II as well as the region between the two sites of each protein. A number of charged residues in the region form salt bridges (Fig. 9B).
Conserved Interaction between TCTP and eEF1B

bridges, including Lys-97p–Glu-167δ–Lys-93p–Glu-170p, Lys-90p–Glu-177δ, Lys-100p–Glu-165δ, and Asp-94p–Arg-178δ, contributing to the buried binding interface. To confirm the role of these residues in the binding, a number of mutants were constructed and used for NMR titration. Mutants including E165A, E166A, E170A, E176K, and D94Q, showed KD values similar to wild type, and E167K, R178D, and K90Q showed a decrease in affinity of severalfold (Table 4). This demonstrates that electrostatic interactions in the region between sites I and II of each protein, forming a continuous interacting surface together with sites I and II of each protein, also contribute to the binding affinity.

The structure model of the complex is in agreement with the thermodynamic parameters obtained from ITC experiments. The large buried interaction surface area in the structure of the complex suggests that a significant decrease in hydration should occur during binding, which is in agreement with the large negative value of the heat capacity change estimated by ITC experiments (Table 2). A large number of electrostatic interactions in the structure of the complex is consistent with the dominant enthalpy change observed in ITC experiments. The apparent thermodynamic parameters obtained from the ITC experiments also reveal that the entropy change is relatively small. Although hydrophobic interactions and dehydoration during binding will result in a positive entropy change, the significant change in dynamics (flexible-to-rigid) of the eEF1B TCTP CAR domain upon binding to TCTP produces a negative entropy change, which results in the small total entropy change.

Interaction of TCTP and eEF1B GEFs Is Conserved in Eukaryotes—TCTP is highly conserved in eukaryotes. Sequence alignment of TCTPs (Fig. 10A) showed the key residues for binding eEF1Bδ are largely conserved in various species. Four of five hydrophobic residues (Ile-92p, Met-96p, Met-115p, Ala-118p, and Ile-122p) except Met-115 in human TCTP site I are hydrophobic residues in all TCTPs. The positively charged residues are also largely conserved, particularly Lys-93p (whose mutation causes the most significant affinity loss with eEF1Bδ) is completely conserved in TCTPs. In TCTP site II, the two key hydrophobic residues (Phe-83 and Met-140 in human TCTP) are always hydrophobic residues in TCTPs. The sequence alignment of various GEFs in the eEF1B complex (including eEF1Bα, which exists in all eukaryotes, eEF1Bδ, which exists only in metazoans, and eEF1Bβ, which exists only in plants (Figs. 1 and 10B)) indicates that all of these proteins have the conserved CAR domain at the N terminus of the GEF domain. Furthermore, the key residues Leu-Phe and surrounding negatively charged residues in eEF1Bδ site I are completely conserved in all eEF1B GEF domains. In eEF1Bδ site II, the hydrophobic residue Tyr-182δ is largely but not completely conserved in all CAR domains. Therefore, both site I of TCTP and site I of all eEF1B GEF CAR domains are conserved in eukaryotes, although site II of each of the proteins is less well conserved. Because it is site I in each protein that is crucial for the interaction, we can therefore speculate that the interaction between TCTP and eEF1B GEFs is conserved in all eukaryotes.

To test the conservation of the interaction between TCTP and eEF1B GEFs, we first checked the interaction between human TCTP and eEF1Bα. NMR titration experiments showed that the CAR domain and the CAR-GEF region of eEF1Bα interact with TCTP, and the CSPs of TCTP and KD values were very similar to those from the titration experiments with eEF1Bδ (Fig. 10, C–F). These results demonstrate that TCTP interacts with eEF1Bα at the same sites as with eEF1Bδ. Such interactions were also detected for TCTP and eEF1Bδ from lower eukaryotes, including the fission yeast S. pombe and the unicellular photosynthetic microalga N. oceanica (Fig. 11). The binding sites on fission yeast TCTP identified by CSP mapping, according to the previous chemical shift assignments of fission yeast TCTP (35), include both site I and site II, the same as the sites on human TCTP. The binding affinities (112 ± 18 μM for S. pombe and 38.4 ± 9.0 μM for N. oceanica) derived from NMR titration are similar (slightly lower) to those for human TCTP-eEF1Bα/δ interactions. These results imply that the interaction between TCTP and eEF1B GEFs is conserved in all eukaryotes.

DISCUSSION

In this study, we demonstrate that the CAR domain of eEF1Bδ (residues 153–192), which is structurally independent of the C-terminal GEF domain, is responsible for binding to TCTP through conserved hydrophobic and electrostatic interactions. The interactions are conserved for TCTP and all GEFs of the eEF1B complex, including eukaryotically conserved eEF1Bα and plant-specific eEF1Bδ. Thus, the CAR domain is a pivotal region for the regulation of different eEF1B subunits in performing GEF activity, and the involvement of TCTP in the protein translation machinery likely represents one of the primary cellular functions of TCTP in all eukaryotes.

The finding that TCTP binds to the CAR domain instead of the GEF domain of eEF1Bδ raises the question of how TCTP inhibits the GEF activity of eEF1Bδ. According to the structure of the eEF1Bα-eEF1A complex (Protein Data Bank codes 1F60 and 1IIF) (16, 17), the catalytic residues of eEF1Bα are located at the C terminus, and a conserved lysine residue at the second position from the C terminus of eEF1Bα disrupts the interaction of Mg2+ with eEF1A and GDP, resulting in the release of Mg2+ and GDP from eEF1A. The C and N termini of the eEF1Bα GEF domain form an antiparallel β-sheet; thus, the CAR domain, which is at the N terminus of the GEF domain, is also spatially close to the GDP/Mg2+-binding site of eEF1A domain I. When the 20-kDa TCTP protein binds to the CAR domain of eEF1Bα, TCTP will likely impede the release of GDP by steric hindrance. This inhibition mechanism is different from classic guanine nucleotide dissociation inhibitors that inhibit the nucleotide release from GTPases by competing with the nucleotide exchange factors (36, 37).

Our data demonstrate that the α-hairpin-containing site I of TCTP plays a key role in the interaction with eEF1B GEFs. It has been proposed that the α-hairpin of TCTP plays a key role in many interactions and functions of TCTP (9, 12, 38–41). However, all of these reports lack structural information about the interaction, and some of them are contradictory. For example, several researchers reported that TCTP physically interacts with p53 (9, 39, 42). However, one paper reported that p53 binds to the α-hairpin of TCTP (39), although another paper reported that p53 binds to the N- and C-terminal regions of TCTP (42). All of them used fragments of TCTP to detect the
interacting regions, which are probably problematic because structural studies indicate that TCTP is a single domain protein and fragments are unlikely to fold well or reflect the real interactions of the intact protein (6, 18, 22). Many other studies of TCTP-protein interactions also used fragments of TCTP to identify the binding regions (12, 38, 43–47), and most of them assume a “three-domain” view of TCTP consisting of an N-terminal “domain,” a central helical domain and a C-terminal domain. The binding regions identified in these studies probably also need further confirmation by NMR or crystallographic methods using intact TCTP because the fragments may be incorrectly folded or unfolded.

The conserved interaction of TCTP with the eEF1B complex suggests the involvement of TCTP in the protein translation

*Conserved Interaction between TCTP and eEF1B*
machinery. In fact, by carefully analyzing the literature, we found several additional pieces of evidence for the involvement of TCTP in protein translation. In 2000, before discovery of the interaction between TCTP and the eEF1 complex, Brown et al. (48) used support vector machines to classify budding yeast genes based on microarray gene expression, which classified TCTP as the cytoplasmic ribosome class, suggesting that TCTP expression is co-regulated with the ribosome. Later, in 2006, Fleischer et al. (49) screened 77 uncharacterized proteins, including TCTP, associated with the ribosome in yeast. Recently, Atkinson et al. (50) reported that eEF1A and eEF1B are not completely conserved in eukaryotes, and some species contain an EF1A-like protein (EFL) that replaces eEF1A and eEF1B. Interestingly, when we searched TCTP homologues in these eEF1A-lacking species, we found that none of them contains a TCTP-homologue gene, except *Emiliania huxleyi*. For those “intermediate” species containing both EFL and eEF1A (11 species reported), most of them lack both eEF1B and TCTP, except the following three species: *Symbiodinium sp.* CladeC that contains a TCTP homologue only and *Guillardia theta* and *Thecamonas trahens* that contain both eEF1B and TCTP homologues. Therefore, it is likely that TCTP and the eEF1A-eEF1B complex have co-evolved, which suggests that they are homologues. Therefore, it is likely that TCTP and the eEF1A-eEF1B complex have co-evolved, which suggests that they are tightly correlated in function.

Our study demonstrates for the first time that TCTP is involved in a conserved eukaryotic cellular function by interacting with GEFs of the eEF1B complex. The structural and interaction data provide insight into the mechanism of TCTP function. Many interactions have been reported for TCTP without structural information. Our study provides a paradigm for further studies of the structural mechanism of these interactions.

Acknowledgments—NMR experiments were carried out at the Core Facility for Protein Research, Institute of Biophysics, Chinese Academy of Sciences, and the Beijing NMR Center or the NMR Facility of the National Center for Protein Sciences at Peking University. We thank Dr. Xuehui Liu and Dr. Yuanyuan Chen, both from the Core Facility for Protein Research, Institute of Biophysics, for help with CLEANEX-PM and ITC experiments, respectively.
